

Online Software Evaluation Report

TITLE : 100 Collaborative Products and their Uses
REPORT # : R21/0310
AUTHOR(S) : Jon Baggaley, Jim Depow, Jim Klaas & Norine Wark
DATE : October 2003

Abstract

The report highlights the trends that have emerged from the evaluation of 100 online collaborative tools in this series of reports so far (2001-03). Emphasis is placed upon the special requirements of distance education (DE) users of collaborative tools, in the selection of online text/audio/video-conferencing, polling and whiteboard methods, and integrated course delivery systems combining all of these features. The technical and didactic skills for using collaborative tools effectively are illustrated, in relation to a standard freeware for online audio-conferencing.

Introduction

Many collaborative software tools are initially developed for other markets: e.g. the lucrative corporate training industry and for campus-based uses. The criteria for software selection in these contexts, however, and those of DE usage, are quite different. Software that works well in an expensively-equipped central laboratory, for example, may not work at all for students who are restricted to using less sophisticated home computers in their online studies; and the software vendors are often unaware of, and fail to acknowledge these problems in promoting their products to the DE sector. DE students, therefore, provide an important perspective on the tools' benefits and shortcomings, and enable the DE teacher to select software that works efficiently on a wide range of student Internet platforms. The current series of evaluation reports and its accompanying web site were established in late 2001, to identify the available products and services for making online DE optimally interactive and collaborative, and to evaluate the tools from the DE student viewpoint. As the project ends its second year, the number of collaborative tools reviewed so far has reached 100. We take this opportunity to identify trends observed during the evaluation project to date.

Types of Collaborative Tool

- A) Text-conferencing. This is the oldest and most basic form of online conferencing. One of the pioneering text-conference softwares was *CoSy*, conceived at the University of Guelph in 1983. Today's text-conferencing tools range from simple threaded formats to elaborate systems involving user and administrative support features. Given the choice, the DE students surveyed during the current project have invariably chosen simple text-conference formats requiring little learning effort (Report #8).
- B) Audio-conferencing. 'Internet telephone' tools became available in the mid-90s, usually restricted to one-on-one conversations. Many early audio products required the two participants to check one another's Internet Protocol address (IP) in order to connect. Since one's IP can differ with each Internet connection, this method tended to be cumbersome. Today's audio-

conferencing methods provide access to numerous online participants at the click of a single icon, and usually provide parallel 'text-box' facilities in support of the audio discussion.

- C) Video-conferencing. Most of today's audio-conferencing tools also provide the option to make one's web-camera image available to the other participants. This feature can cause computers with lesser RAM memory to freeze up, and in most DE situations the video image is a novelty that soon loses its appeal. Numerous freeware messaging products now include a video-conferencing option with good AV quality.
- D) Whiteboards. These tools provide a blank display on which conferencing participants can type, draw with a mouse or graphics tablet, visit web sites together (co-browsing), and contribute simultaneously to the display's modification. Standard whiteboard tools are available online at no cost, allowing remote users to collaborate on projects while conversing using an A/V-conferencing tool.
- E) Polling tools. Numerous software products and services allow the user to create questionnaires, surveys, quizzes, and other types of poll, and to feed the results back to the respondents either instantly or subsequently. These tools can give the DE teacher and students rapid, nonverbal analyses of a group's thinking. Polls can be designed in advance or administered 'on the fly', though need to be designed carefully in order to ensure that they yield valid and reliable conclusions.
- F) Course delivery systems. During the past five years, all of the above features have been combined into integrated software packages for the administration of online learning processes. (Report #5 in the series identified 31 such products.) Their aggressive marketing and high cost have become major issues in the educational sector. This trend is similar to that observed in the selection of educational hardware in the 1970s, when separate gadgets (e.g. tape-recorders and slide-projectors) were combined into single devices. The relative clumsiness and high cost of these integrated hardware systems caused the market to return to more flexible 'stand-alone' gadgets. During the 2000s, the online software market is moving in the same direction with the development of integrated 'open source' tools (Reports #24 and 25).

Best Practices in Online Conferencing

The evaluations reported in the series so far have had a direct impact on the practices of the graduate school that hosts the project: Athabasca University's Masters in Distance Education (MDE) Programme. In the late 1990s, MDE instructors used asynchronous, text-based methods of online collaboration alone. Since 2000, their courses have adopted a selection of course delivery systems (e.g. *Elluminate*, *WebCT*, and *Wimba*), and an increasing range of freeware tools (e.g. *GroupBoard*, *PalTalk*, *Sonork*, and *Yahoo Messenger*) which provides similar functions. Six of the 100 products evaluated in 2001-03 have since failed. Otherwise the market has remained stable, while seeing an explosion of new and largely overlapping competitive products. One of the failed products, *FireTalk*, was arguably the most sophisticated audio-conferencing tool yet developed. Its demise indicates that even the most robust technical product can fail owing to market forces, and provides a warning to institutions that may be tempted to lock themselves into an investment in an expensive commercial product, rather than retaining the flexibility that accompanies the use of good-quality freeware.

In most cases, the MDE Programme's software selections are the direct result of the evaluation project's recommendations. The project has provided similar assistance, and a greater awareness of the available collaborative tools, to distance educators and students worldwide. The selection of a good software package, however, only goes part way towards developing effective online practices. Expensive software and freeware alike can be rendered impotent by inefficient usage, and the importance of developing user skills and protocols cannot be overstated. Numerous advisories have been published on the skills of

effective teleconferencing (see the web site's 'Sources' section), although at this stage most of these do not relate to the specific challenges of online conferencing. The online moderator in particular requires a complex set of 'multitasking' skills, similar to those of the TV control room, whose director must continually scrutinize the broadcast output while lining up the stimuli that will be used moments ahead. The software evaluation teams involved in the current project (MDE Programme graduate students) develop these moderating skills in testing the software options, and formulate guidelines for their usage. The following is a list of the recommended 'best moderating practices' based on the research, trials and tribulations of one of these evaluation teams. It relates specifically to the conferencing activities underlying most current online collaborative approaches.

1. Technical pre-meeting:

- a. As far as possible, obtain details of the hardware configurations, connection speeds and operating systems of the conference participants, and ensure that these meet the requirements of the selected software.
- b. Provide the participants with a guide for software downloading, installation and instructions on how to add one another to their user list.
- c. Encourage first-time participants to pre-test the software at least 24 hours before the meeting, including running the 'audio set up wizard' as appropriate.
- d. Urge participants to restart their computers 15 minutes before the conference, and not to open unnecessary applications (e.g. email) during the conference.
- e. Ask participants to log-in to the collaborative area at least 5 minutes before the conference session for a set-up check.

2. Didactic pre-meeting:

- a. Ensure that the participants have a session agenda in advance, specifying the preparation that is required and the session's expectations.
- b. Users should also have a list of participants with their actual names so they can interpret screen ID names.
- c. Groups of 10 or more participants are not recommended for novice moderators, owing to the difficulty of keeping track of their text-box postings and speaking order. Unless instructed otherwise, a few students will dominate the discussion while the majority will 'lurk' (Tolley, 2000).

3. Technical meeting:

- a. Identify one participant as a technical assistant, to send personal text messages to users who are having trouble obtaining or maintaining their connection.
- b. Ask participants to restrict their use of 'text-boxes' to central issues of conference coordination, questions, etc. Side chats can have the distracting effect of 'whispering in class'.
- c. Ask participants not to send the moderator private messages as this will disrupt the main conference, and to send technical comments to the assistant moderator.
- d. If participants invite others to a side chat, or accept such invitations, they must be aware that they may lose the audio connection to the main conference.
- e. Suggest that participants only use a 'hands free' audio option when actually speaking, owing to the feedback it can produce for other participants.
- f. Provide the facilitator with useful short-hand messages (as provided in some software packages).

4. Didactic meeting:

- a. Clarify the protocol for participation. If the audio software program does not feature a 'raised hand' icon, explain the use of shorthand messages (if provided).
- b. Invite participants to state in the text-box if they lose the audio.
- c. Check audio transmission and reception periodically throughout the session, as it may come and go without warning.

- d. Do not talk for extended periods without relaxing the 'talk' button; at times of busy Internet traffic, this will relieve congestion and signal break-up.
 - e. Give the participants time for feedback. Use open-ended questions to encourage discussion, and direct the question to specific individuals if necessary.
 - f. Post agendas, dates, names of articles, web addresses, and other important information in the text-box, in case participants lose audio connection or are have difficulty with spellings, etc.
 - g. Summarize discussion threads in order to clarify audio and text conversations.
 - h. Save text-box transcripts for future reference.
5. Technical post-meeting:
- a. If it is impossible to warn participants in advance of the hardware and connection speeds required by the conferencing software, check with them subsequently about any technical problems they may have experienced. This cross-checking allows the teacher to identify the resources demands of specific collaborative tools, and to diagnose participants' technical problems in using them.
6. Didactic post-meeting:
- a. Provide participants with a supportive bulletin board, or other forms of online communication, in order to facilitate continued reflection and feedback about the learning materials and process.

Conclusions

The above user guidelines illustrate that technical as well as pedagogical skills are essential to the efficient use of online collaborative tools, as they are in the use of any educational medium. Johnston (quoted by Tolley, 2000), states, "We need to take seriously the pedagogical issues arising out of teaching by online courses...But we are some way off mastering this new domain, and in the meantime we need to be mindful of the snags and pitfalls hereabouts. Let us be converted, but by deeds and not by faith alone". The current software evaluation project will continue to uphold this maxim, as a useful teaching and research activity, and to provide support for international distance educators and their students.
