ABSTRACT

An e-learning course may include a number of structural elements that are aggregated into one or more levels. Each higher level may refer to any instance of a lower level. The structural elements include a course, a sub-course, a learning unit, or a knowledge item. The structural elements may include metadata. The structural elements also may include relations between structural elements. The course and its structural elements do not enforce any sequence of structural elements that the learner may use to traverse the course. In addition, the structural elements may be reused and reassembled to form different courses. A content repository is configured to store course data and its structural elements. A content player is configured to access the stored course data and assemble the structural elements.

E-LEARNING COURSE STRUCTURE

This application is a continuation-in-part of, and therefore claims the benefit of U.S. application Ser. No. 101134,676, filed Apr. 30, 2002, and titled E-LEARNING SYSTEM. This application also claims the benefit of U.S. Provisional Application No. 601354,945, filed Feb. 11, 2002, and titled FLEXIBLE INSTRUCTIONAL ARCHITECTURE FOR E-LEARNING. Both U.S. application Ser. No. 101134,676 and U.S. Provisional Application No. 601354,945 are incorporated herein by reference in their entirety for all purposes.

TECHNICAL FIELD

The following description relates generally to e-learning and in particular to e-learning course structure.

BACKGROUND

Systems and applications for delivering computer-based training (CBT) have existed for many years. However, CBT systems historically have not gained wide acceptance. A problem hindering the reception of CBTs as a means of training workers and learners is the compatibility between systems. A CBT system works as a stand-alone system that is unable to use content designed for use with other CBT systems. Early CBTs also were based on hypermedia systems that statically linked content. User guidance was given by annotating the hyperlinks with descriptive information. The trainer could proceed through learning material by traversing the links embedded in the material. The structure associated with the material was very rigid, and the material could not be easily written, edited, or reused to create additional or new learning material.

Newer methods for intelligent tutoring and CBT systems are based on special domain models that must be defined prior to creation of the course or content. Once a course is created, the material may not be easily adapted or changed for different learners’ specific training needs or learning styles. As a result, the courses often fail to meet the needs of the trainer and/or trainer.

The special domain models also have many complex rules that must be understood prior to designing a course. As a result, a course is too difficult for most authors to create who have not undergone extensive training in the use of the system. Even authors who receive sufficient training may find the system difficult and frustrating to use. In addition, the resulting courses may be incomprehensible due to incorrect use of the domain model by the authors creating the course. Therefore, for the above and other reasons, new methods and technology are needed to supplement traditional computer-based training and instruction.

SUMMARY

In one general aspect, content associated with an e-learning course may be divided into two or more structural elements that may be interpreted by a browser. The structural elements may be aggregated into two or more levels, where a higher level may refer to any instance of a lower level. The structural elements may be assembled into a course.

The lowest level structural element is a knowledge item. The knowledge item illustrates or tests an aspect of a topic. The knowledge item may include one or more of a test, a table, an illustration, a graphic, an animation, an audio clip, and a video clip.

Another structural element is a learning unit, which may refer to one or more knowledge items to represent a thematically-coherent unit of information.

Another structural element is a sub-course, which may refer to one or more of a knowledge item, a learning unit, and a sub-course.

Another structural element is a course, which may refer to one or more of a knowledge item, a learning unit, and a sub-course.

The structural elements may be tagged with metadata to search and assemble the structural elements. The metadata may be knowledge of orientation, knowledge of explanation, knowledge of reference, and knowledge of action. The metadata also may be a competency to indicate the performance of a learner that traverses the course.

A relation may be used to indicate dependencies between structural elements. The relation may be directional (i.e., true in one direction only) or non-directional. The relation may be subject taxonomic or non-subject taxonomic.

The subject taxonomic relation may be hierarchical or associative. The hierarchical relation may be a part/whole relation or an abstraction relation. The associative relation may be one of determines, side-by-side, alternative to, opposite to, precedes, context of, process of, values, means of, and affinity.

The non-subject taxonomic relation may be prerequisite of or belongs to.

The course and its structural elements do not enforce any sequence of structural elements that the learner may use to traverse the course. In addition, the structural elements may be reused and reassembled to form different courses.

A content repository may be configured to store course data and its structural elements. A content player may access the stored course data and assemble the structural elements.

Other features and advantages will be apparent from the description, the drawings, and the claims.

DESCRIPTION OF DRAWINGS

FIG. 1 is an exemplary content aggregation model. FIG. 2 is an example of an ontology of knowledge types. FIG. 3 is an example of a course graph for e-learning. FIG. 4 is an example of a sub-course graph for e-learning. FIG. 5 is an example of a learning unit graph for e-learning. FIGS. 6 and 7 are exemplary block diagrams of e-learning systems. FIG. 8 is an example showing v as the vertex that represents the learning unit L̅ where v₁v₉ are the vertices. Like reference symbols in the various drawings indicate like elements.

DETAILED DESCRIPTION

E-learning Content Structure

The e-learning system and methodology structures content so that the content is reusable and flexible. For example, the content structure allows the creator of a course to reuse existing content to create new or additional courses. In addition, the content structure provides flexible content delivery that may be adapted to the learning styles of different learners.

E-learning content may be aggregated using a number of structural elements arranged at different aggregation levels. Each higher level structural element may refer to any instances of all structural elements of a lower level. At its
lowest level, a structural element refers to content and may not be further divided. According to one implementation shown in FIG. 1, course material 100 may be divided into four structural elements: a course 110, a sub-course 120, a learning unit 130, and a knowledge item 140.

Starting from the lowest level, knowledge items 140 are the basis for the other structural elements and are the building blocks of the course content structure. Each knowledge item 140 may include content that illustrates, explains, practices, or tests an aspect of a thematic area or topic. Knowledge items 140 typically are small in size (i.e., of short duration, e.g., approximately five minutes or less).

A number of attributes may be used to describe a knowledge item 140, such as, for example, a name, a type of media, and a type of knowledge. The name may be used by a learning system to identify and locate the content associated with a knowledge item 140. The type of media describes the form of the content that is associated with the knowledge item 140. For example, media types include a presentation type, a communication type, and an interactive type. Apresentation media type may include a text, a table, an illustration, a graphic, an image, an animation, an audio clip, and a video clip. A communication media type may include a chat session, a group (e.g., a newsgroup, a team, a class, and a group of peers), an email, a short message service (SMS), and an instant message. An interactive media type may include a computer based training, a simulation, and a test.

A knowledge item 140 also may be described by the attribute of knowledge type. For example, knowledge types include knowledge of orientation, knowledge of action, knowledge of explanation, and knowledge of source/reference. Knowledge types may differ in learning goal and content. For example, knowledge of orientation offers a point of reference to the learner, and, therefore, provides general information for a better understanding of the structure of interrelated structural elements. Each of the knowledge types are described in further detail below.

Knowledge items 140 may be generated using a wide range of technologies, however, a browser (including plug-in applications) should be able to interpret and display the appropriate file formats associated with each knowledge item. For example, markup languages (such as a Hypertext Markup language (HTML), a standard generalized markup language (SGML), a dynamic HTML (DHTML®), or an extensible markup language (XML)), JAVA® (a client-side scripting language), and/or FLASH® may be used to create knowledge items 140.

HTML may be used to describe the logical elements and presentation of a document, such as, for example, text, headings, paragraphs, lists, tables, or image references.

Flash may be used as a file format for FLASH® movies and as a plug-in for playing FLASH® files in a browser. For example, FLASH® movies using vector and bitmap graphics, animations, transparencies, transitions, MP3 audio files, input forms, and interactions may be used. In addition, FLASH® allows a pixel-precise positioning of graphical elements to generate impressive and interactive applications for presentation of course material to a learner.

Learning units 130 may be assembled using one or more knowledge items 140 to represent, for example, a distinct, thematically-coherent unit. Consequently, learning units 130 may be considered containers for knowledge items 140 of the same topic. Learning units 130 also may be considered relatively small in size (i.e., duration) though larger than a knowledge item 140.

Sub-courses 120 may be assembled using other sub-courses 120, learning units 130, and/or knowledge items 140. The sub-course 120 may be used to split up an extensive course into several smaller subordinate courses. Sub-courses 120 may be used to build an arbitrarily deep nested structure by referring to other sub-courses 120.

Courses may be assembled from all of the subordinate structural elements including sub-courses 120, learning units 130, and knowledge items 140. To foster maximum reuse, all structural elements should be self-contained and context free.

Structural elements also may be tagged with metadata that is used to support adaptive delivery, reusability, and search/retrieval of content associated with the structural elements. For example, learning object metadata (LOM) defined by the IEEE "Learning Object Metadata Working Group" may be attached to individual course structure elements. The metadata may be used to indicate learner competencies associated with the structural elements. Other metadata may include a number of knowledge types (e.g., orientation, action, explanation, and resources) that may be used to categorize structural elements.

As shown in FIG. 2, structural elements may be categorized using a didactical ontology 200 of knowledge types 201 that includes orientation knowledge 210, action knowledge 220, explanation knowledge 230, and reference knowledge 240. Orientation knowledge 210 helps a learner to find their way through a topic without being able to act in a topic-specific manner and may be referred to as "know what." Action knowledge 220 helps a learner to acquire topic related skills and may be referred to as "know how." Explanation knowledge 230 provides a learner with an explanation of why something is the way it is and may be referred to as "know why." Reference knowledge 240 teaches a learner where to find additional information on a specific topic and may be referred to as "know where."

The four knowledge types (orientation, action, explanation, and reference) may be further divided into a fine grained ontology as shown in FIG. 2. For example, orientation knowledge 210 may refer to sub-types 250 that include a history, a scenario, a fact, an overview, and a summary. Action knowledge 220 may refer to sub-types 260 that include a strategy, a procedure, a rule, a principle, an order, a law, a comment on law, and a checklist. Explanation knowledge 230 may refer to sub-types 270 that include an example, a intention, a reflection, an explanation of why or what, and an argumentation. Reference knowledge 240 may refer to sub-types 280 that include a reference, a document reference, and an archival reference.

Dependencies between structural elements may be described by relations when assembling the structural elements at one aggregation level. A relation may be used to describe the natural, subject-taxonomic relation between the structural elements. A relation may be directional or non-directional. A directional relation may be used to indicate that the relation between structural elements is true only in one direction. Directional relations should be followed. Relations may be divided into two categories: subject-taxonomic and non-subject taxonomic.

Subject-taxonomic relations may be further divided into hierarchical relations and associative relations. Hierarchical relations may be used to express a relation between structural elements that have a relation of subordination or superordination. For example, a hierarchical relation between the knowledge items A and B exists if B is part of A. Hierarchical relations may be divided into two categories: the part/whole relation (i.e., "has part") and the abstrac-
tion relation (i.e., "generalizes"). For example, the part/whole relation "A has part B" describes that B is part of A. The abstraction relation "A generalizes B" implies that B is a specific type of A (e.g., an aircraft generalizes a jet or a jet is a specific type of aircraft).

Associative relations may be used refer to a kind of relation of relevancy between two structural elements. Associative relations may help a learner obtain a better understanding of facts associated with the structural elements. Associative relations describe a manifold relation between two structural elements and are mainly directional (i.e., the relation between structural elements is true only in one direction). Examples of associative relations include "determines," "side-by-side," "alternative to," "opposite to," "precedes," "context of," "process of," "values," "means of," and "affinity."

The "determines" relation describes a deterministic correlation between A and B (e.g., B causally depends on A). The "side-by-side" relation may be viewed from a spatial, conceptual, theoretical, or ontological perspective (e.g., A side-by-side with B is valid if both knowledge objects are part of a superordinate whole). The side-by-side relation may be subdivided into relations, such as "similar to," "alternative to," and "analogous to." The "opposite to" relation implies that two structural elements are opposite in reference to at least one quality. The "precedes" relation describes a temporal succession of events (e.g., A occurs in time before B (and not that A is a prerequisite of B)). The "context of" relation describes the factual and situational relationship on a basis of which one of the related structural elements may be derived. An "affinity" between structural elements suggests that there is a close functional correlation between the structural elements (e.g., there is an affinity between books and the act of reading because reading is the main function of books).

Non Subject-Taxonomic relations may include the relations "prerequisite of" and "belongs to." The "prerequisite of" and the "belongs to" relations do not refer to the subject-taxonomic interrelations of the knowledge to be imparted. Instead, these relations refer to the progress of the course in the learning environment (e.g., as the learner traverses the course). The "prerequisite of" relation is directional whereas the "belongs to" relation is non-directional. Both relations may be used for knowledge items 140 that cannot be further subdivided. For example, if the size of the screen is too small to display the entire content on one page, the page displaying the content may be split into two pages that are connected by the relation "prerequisite of."

Another type of metadata is competencies. Competencies may be assigned to structural elements, such as, for example, a sub-course 120 or a learning unit 130. The competencies may be used to indicate and evaluate the performance of a learner as the learner traverses the course material. A competency may be classified as a cognitive skill, an emotional skill, a sensori-motor skill, or a social skill.

The content structure associated with a course may be represented as a set of graphs. A structural element may be represented as a node in a graph. Node attributes are used to convey the metadata attached to the corresponding structural element (e.g., a name, a knowledge type, a competency, and/or a media type). A relation between two structural elements may be represented as an edge. For example, FIG. 3 shows a graph 300 for a course. The course is divided into four structural elements or nodes (310, 320, 330, and 340): three sub-courses (e.g., knowledge structure, learning environment, and tools) and one learning unit (e.g., basic concepts). A node attribute 350 of each node is shown in brackets (e.g., the node labeled "Basic concepts") has an attribute that identifies it as a reference to a learning unit. In addition, an edge 380 expressing the relation "context of" has been specified for the learning unit with respect to each of the sub-courses. As a result, the basic concepts explained in the learning unit provide the context for the concepts covered in the three sub-courses.

FIG. 4 shows a graph 400 of the sub-course "Knowledge structure" 350 of FIG. 3. In this example, the sub-course "Knowledge structure" is further divided into three nodes (410, 420, and 430): a learning unit (e.g., on relations) and two sub-courses (e.g., covering the topics of methods and knowledge objects). The edge 440 expressing the relation "determines" has been provided between the structural elements (e.g., the sub-course "Methods" determines the sub-course "Knowledge objects" and the learning unit "Relations"). In addition, the attributes 450 of each node is shown in brackets (e.g., sub-courses) and "Knowledge objects" have the attribute identifying them as references to other sub-courses; node "Relations" has the attribute of being a reference to a learning unit.

FIG. 5 shows a graph 500 for the learning unit "Relations" 490 shown in FIG. 4. The learning unit includes six nodes (510, 515, 520, 525, 530, 535, 540, and 545): six knowledge items (i.e., "Associative relations (1)", "Associative relations (2)", "Test on relations", "Hierarchical relations", "Non subject-taxonomic relations", and "The different relations"). An edge 547 expressing the relation "prerequisite of" has been provided between the knowledge items "Associative relations (1)" and "Associative relations (2)." In addition, attributes 550 of each node are specified in brackets (e.g., the node "Hierarchical relations" includes the attributes "Example" and "Picture").

E-learning Strategies

The above-described content aggregation and structure associated with a course does not automatically enforce any sequence that a learner may use to traverse the content associated with the course. As a result, different sequencing rules may be applied to the same course structure to provide different paths through the course. The sequencing rules applied to the knowledge structure of a course are learning strategies. The learning strategies may be used to pick specific structural elements to be suggested to the learner as the learner progresses through the course. The learner or supervisor (e.g., a tutor) may select from a number of different learning strategies while taking a course. In turn, the selected learning strategy considers both the requirements of the course structure and the preferences of the learner.

In the classical classroom, a teacher determines the learning strategy that is used to learn course material. For example, in this context the learning progression may start with a course orientation, followed by an explanation (with examples), an action, and practice. Using the e-learning system and methods, a learner may choose between one or more learning strategies to determine which path to take through the course. As a result, the progression of learners through the course may differ.

Learning strategies may be created using macro-strategies and micro-strategies. A learner may select from a number of different learning strategies when taking a course. The learning strategies are selected at run time of the presentation of course content to the learner (and not during the design of the knowledge structure of the course). As result, course authors are relieved from the burden of determining a sequence or an order of presentation of the course material.
Instead, course authors may focus on structuring and annotating the course material. In addition, authors are not required to apply complex rules or Boolean expressions to domain models thus minimizing the training necessary to use the system. Furthermore, the course material may be easily adapted and reused to edit and create new courses.

Macro-strategies are used in learning strategies to refer to the coarse-grained structure of a course (i.e., the organization of sub-courses 120 and learning units 130). The macro-strategy determines the sequence that sub-courses 120 and learning units 130 of a course are presented to the learner. Basic macro-strategies include "inductive" and "deductive," which allow the learner to work through the course from the general to the specific or the specific to the general, respectively. Other examples of macro-strategies include "goal-based, top-down," "goal-based, bottom-up," and "table of contents."

Goal-based, top-down follows a deductive approach. The structural hierarchies are traversed from top to bottom. Relations within one structural element are ignored if the relation does not specify a hierarchical dependency. Goal-based bottom-up follows an inductive approach by doing a depth first traversal of the course material. The table of contents simply ignores all relations.

Micro-strategies, implemented by the learning strategies, target the learning progression within a learning unit. The micro-strategies determine the order that knowledge items of a learning unit are presented. Micro-strategies refer to the attributes describing the knowledge items. Examples of micro-strategies include "orientation only," "action oriented," "explanation-oriented," and "table of contents."

The micro-strategy "orientation only" ignores all knowledge items that are not classified as orientation knowledge. The "orientation only" strategy may be best suited to implement an overview of the course. The micro-strategy "action oriented" first picks knowledge items that are classified as action knowledge. All other knowledge items are sorted in their natural order (i.e., as they appear in the knowledge structure of the learning unit). The micro-strategy "explanation oriented" is similar to action oriented and focuses on explanation knowledge. Orientation oriented is similar to action oriented and focuses on orientation knowledge. The micro-strategy "table of contents" operates like the macro-strategy table of contents (but on a learning unit level).

In one implementation, no dependencies between macro-strategies and micro-strategies exist. Therefore, any combination of macro and micro-strategies may be used when taking a course. Application of learning strategies to the knowledge structure of a course is described in further detail below.

E-learning System

As shown in FIG. 6, an e-learning architecture 600 may include a learning station 610 and a learning system 620. The learner may access course material using a learning station 610 (e.g., using a learning portal). The learning station 610 may be implemented using a work station, a computer, a portable computing device, or any intelligent device capable of executing instructions and connecting to a network. The learning station 610 may include any number of devices and/or peripherals (e.g., displays, memory/storage devices, input devices, interfaces, printers, communication cards, and speakers) that facilitate access to and use of course material.

The learning station 610 may execute any number of software applications, including an application that is configured to access, interpret, and present courses and related information to a learner. The software may be implemented using a browser, such as, for example, NETSCAPE® COMMUNICATOR®, MICROSOFT® INTERNET EXPLORER®, or any other software application that may be used to interpret and process a markup language, such as HTML, SGML, DHTML®, or XML.

The browser may also include software plug-in applications that allow the browser to interpret, process, and present different types of information. The browser may include any number of application tools, such as, for example, JAVA®, ACTIVE X®, JAVASCRIPT®, AND FLASH®.

The browser may be used to implement a learning portal that allows a learner to access the learning system 620. A link 621 between the learning portal and the learning system 620 may be configured to send and receive signals (e.g., electrical, electromagnetic, or optical). In addition, the link may be a wireless link that uses electromagnetic signals (e.g., radio, infrared, or microwave) to convey information between the learning station and the learning system.

The learning system may include one or more servers. As shown in FIG. 6, the learning system 620 includes a learning management system 623, a content management system 625, and an administration management system 627. Each of these systems may be implemented using one or more servers, processors, or intelligent network devices.

The administration system may be implemented using a server, such as, for example, the SAP® R/3 4.6 C LSO Add-On. The administration system may include a database of learner accounts and course information. For example, the learner account may include demographic data about the learner (e.g., a name, an age, a sex, an address, a company, a school, an account number, and a bill) and his/her progress through the course material (e.g., places visited, tests completed, skills gained, knowledge acquired, and competency using the material). The administration system also may provide additional information about courses, such as the courses offered, the author/instructor of a course, and the most popular courses.

The content management system may include a learning content server. The learning content server may be implemented using a WebDAV server. The learning content server may include a content repository. The content repository may store course files and media files that are used to present a course to a learner at the learning station. The course files may include the structural elements that make up a course and may be stored as XML files. The media files may be used to store the content that is included in the course and assembled for presentation to the learner at the learning station.

The learning management system may include a content player. The content player may be implemented using a server, such as, an SAP® J2EE Engine. The content player is used to obtain course material from the content repository. The content player also applies the learning strategies to the obtained course material to generate a navigation tree for the learner. The navigation tree is used to suggest a route through the course material for the learner and to generate a presentation of course material to the learner based on the learning strategy selected by the learner.

The learning management system also may include an interface for exchanging information with the administration system. For example, the content player may update the learner account information as the learner progresses through the course material.
Course Navigation

The structure of a course is made up of a number of graphs of the structural elements included in the course. A navigation tree may be determined from the graphs by applying a selected learning strategy to the graphs. The navigation tree may be used to navigate a path through the course for the learner. Only parts of the navigation tree are displayed to the learner at the learning portal based on the position of the learner within the course.

As described above, learning strategies are applied to the static course structure including the structural elements (nodes), metadata (attributes), and relations (edges). This data is created when the course structure is determined (e.g., by a course author). Once the course structure is created, the course player processes the course structure using a strategy to present the material to the learner at the learning portal.

To process courses, the course player grants strategies access to the course data and the corresponding attributes. The strategy is used to prepare a record of predicates, functions, operations, and orders that are used to calculate navigation suggestions, which is explained in further detail below.

The content player accesses files (e.g., XML files storing course graphs and associated media content) in the content repository and applies the learning strategies to the files to generate a path through the course. By applying the learning strategies the content producer creates a set of course-related graphs (which is simply an ordered list of nodes) that are used to generate a navigation tree of nodes. The set of nodes may be sorted to generate an order list of nodes that may be used to present a path through the material for a learner. In general graphs and strategies may "interact" in the following ways:

1. A strategy implements a set of Boolean predicates that can be applied to graph nodes. For example: isCompleted (node).
2. A strategy may be informed by an event that some sort of action has been performed on a graph node. For example: navigated (node).
3. A strategy may provide functions that are used to compute new node sets for a given node. For example: NavigationNodes (node).
4. A strategy provides an ordering function that turns node sets computed number 3 into ordered lists.
5. A strategy may decide to alter certain strategy-related node attributes. For example: node.setVisited (true).

Note that the last point is used because a strategy does not keep any internal state. Instead, any strategy-related information is stored in graph nodes' attributes allowing strategies to be changed "on the fly" during graph traversal.

As described there are sets of nodes that may be used to generate a path through a course. One set of nodes is "navigation nodes." Navigation nodes may include all nodes that the strategy identifies that may be immediately reached from the current node. In other words, the navigation nodes represent potential direct successors from a current node. Another set of nodes are "start nodes." Start nodes are potential starting points when entering a new graph. The more starting points this set contains, the more choices a learner has when entering the unit. As a consequence, any strategy should implement at least two functions that can compute these sets and the ordering function that transforms those sets into ordered lists. The functions are described in further detail below using the following examples.

In the following examples, these definitions are used:
- C is the set of all courses.
- G is a set of graphs.

V is a set of vertices (e.g., knowledge items, references to learning units, references to sub courses, and test)
- Vertices are used when talking about graphs in a mathematical sense (whereas nodes may used to refer to the resulting course structure)
- E is a set of edges (e.g., relations types as used in a mathematical sense)
- G is the set of graph types such that:
  - sc=sub-course; and
  - lu=learning unit.
- V is the starting vertex of e; V is the end vertex of e; and tr is the relation type of e.
11

A predicate is a mapping \( p: V \rightarrow \text{BOOL} \) that assigns a value \( p(v) \in \text{BOOL} \) to each vertex \( v \in V \). Therefore:

\[
b_p(v) = p(v).
\]

An order is a mapping \( \text{ord}: V \times V \rightarrow \text{BOOL} \) that assigns a value \( \text{ord}(v, w) \) to each pair of vertices \( v, w \in V \). Therefore:

\[
b_{\text{ord}}(v, w) = \text{ord}(v, w).
\]

The mapping \( \text{sort}: V^n \rightarrow V^n \) is a sorting function from a set of vertices \( V^n \) to a set of vertices \( V^n \) with the order \( \text{ord} \), provided that:

\[
(v_1, \ldots, v_n) = \text{sort}(V^n, \text{ord}) \\
\text{if } i < j \text{ then } v_i \neq v_j
\]

for \( i \leq j \).

The following description explains the use of attributes. Attributes are used to define and implement the learning strategies.

Let \( g = (V, E, \text{comp}, \text{sc}) \) be a graph with the following attributes:

\[
g_{\text{nodes}} = V \\
g_{\text{type}} = \text{type} \\
g_{\text{comp}} = \text{comp}
\]

Let \( v = (v, v, v, v, v, v) \) be a vertex with the following attributes:

\[
v_{\text{visited}} = \text{vs}, v_{\text{mscore}} = \text{mscore}, v_{\text{ascore}} = \text{ascore}, v_{\text{contentType}} = \text{tc}, v_{\text{knowledgeType}} = \text{tk}, v_{\text{graph}} = \text{g}, v_{\text{testType}} = \text{tt}, v_{\text{maxScore}} = \text{mscore}, v_{\text{ActScore}} = \text{sc}
\]

Operations provide information to the chosen strategy about particular events that occur during navigation of a course. The strategy may use them to change the attributes.

The operations are:

\[
\text{navigate}(v), \text{maxScore}(v, \text{actScore}) \]

The runtime environment calls this operation as soon as the vertex \( v \) is navigated during the navigation of the course.

The runtime environment calls this operation if the vertex \( v \) is a test vertex and has been done. \( \text{maxScore} \) contains the maximum possible score, \( \text{ActScore} \) the score actually attained.

If a vertex in a learning unit, which means that \( v_{\text{graph}} = \text{lu} \), then the micro-strategy computes these operations. The macro-strategy is responsible for all other vertices.

The runtime environment uses the sorting function to order the navigation sets that have been computed. The order determines the sequence in which the vertices are to be drawn. The "most important" vertex (e.g., from the strategy's point of view) is placed at the start of the list (as the next vertex suggested). The strategies implement these sorting functions and the runtime environment provides them.

The following examples of sorting functions may be defined:

\[
\text{sortNav}(V)
\]

Predicates are "dynamic attributes" of vertices. The strategy computes the dynamic attributes for an individual vertex when necessary.

The following are examples of predicates:

\[
\text{visited}(v): v \text{ has already been visited}; \text{Suggested}(v): v \text{ is suggested}; \text{CanNavigate}(v): v \text{ can be navigated}; \text{Done}(v): v \text{ is done}
\]

If a vertex is within a learning unit (i.e., \( v_{\text{graph}} = \text{lu} \)), then the micro-strategy is used to compute the predicates.

The macro-strategy that is chosen is responsible for determining all other vertices.

Functions are used to compute the navigation sets (vertices that are displayed). A function should return a set of vertices. The strategies implement the functions.

For example, the following functions are:

\[
\text{StartNodes}(g) = \{ v \in V : \text{v is a starting vertex of g} \}
\]

\[
\text{NextNodes}(v) = \{ v \in V : \text{v is a successor of v} \}
\]

\[
\text{AutoComplete}(g) = \{ v \in V : \text{v is an automatically computed vertex} \}
\]

The macro-strategy selects the appropriate (selected) micro-strategy. The strategies implement the functions.
The following is an example of how a top-down (deductive) learning strategy may be realized.

The predicates for the top-down strategy may be defined as follows:

- Visited(v): v.visited
- The vertex's "visited" attribute is set.

The functions for the top-down strategy may be defined as follows:

- Suggested(v): ∀(v,v, tr) ∈ E such that tr = prerequisite we have:
  Done(v) = true
- All of the vertex's prerequisites are satisfied.
- CanNavigate(v): Suggested(v)
- Is used in this example like Suggested.
- Done(v):
  \( (v.contentType \{ sc, lu \} \land v.contentGraph \neq 0 \leq LCOMP)v \)
  \( (v.contentType = \text{test} \land v.visited = true \land (\forall v \in \text{StartNodes}(v.contentGraph): \text{Done}(v) = true)) \lor \)
  \( (c.contentType = \text{test} \land (v.ascore \neq 2) \land v.score) \)
- The vertex v is considered done if at least one of the following conditions holds:
  - It includes a learning unit or sub-course that has at its disposal a nonempty set of competences that the learner already possesses;
  - It does not contain a test, is visited, and all of the content graph's starting vertices have been done; and/or
  - It deals with a test and at least half of the maximum score has been attained.

The functions for the top-down strategy may be defined as follows:

- \( \text{StartNodes}(g) = \{ \begin{align*}
  c &= \text{undefined}: 0 \\
  g.gtype &= \text{lu}, \text{mc} \in \text{StartNodes}(g) \\
  g.gtype &= \text{sc}; v \in V_2 \mid (v, v, tr) \in E; (v -> v). \}
\end{align*} \)
- If g is undefined, which means that vertex does not have any content graphs, then the set is empty.
- If g is a learning unit, the StartNodes() function of the chosen micro-strategy will be used.
- If g is a sub-course, all vertices that do not have any hierarchical relations referring to them will be returned.

NextNodes(v) = \{ d ∈ \text{V}_2 \mid \text{contentGraph} (v, \text{V}_2) \} \cup \text{StartNodes}(v.contentGraph)
Using these definitions the function $\langle V_1, V_2 \rangle \rightarrow \text{bool}$ may be defined as follows:

$$\forall v_1, v_2 \in V_1 \land v_1, v_2 \in V_2: \langle v_1, v_2 \rangle = \text{true} \iff$$

$$v_1, \text{contentType} = \text{ist} \land$$
$$\exists v \in V_2: \{v_1, v, \text{prereq} \in E_1 \land v, \text{contentType} = \text{ist} \land v_1 \land v_2 \}$$
$$\lor v_1, \text{contentType} = \text{ist} \land$$
$$\exists v \in V_2: \{v_1, v, \text{prereq} \in E_1 \land v, \text{contentType} = \text{ist} \land v_1 \land v_2 \}$$

11. Search for all vertices in $v \in V_{\text{preTest}}$, the vertex $v^*$, such that

$$v^*, \text{contentType} = \text{ist} \land$$
$$\exists v \in V_2: \{v^*, v, \text{prereq} \in E_1 \land v, \text{contentType} = \text{ist} \land v^* \land v \}$$

Note, if $g_1 = g_2$, then it is obvious that $V_1 \subseteq V_2$ in case $E_1 \subseteq E_2$, $A_1 \subseteq A_2$, and $\text{comp}_1 = \text{comp}_2$. In addition, in case 3, a situation is prevented in which no direct relation between the vertices exist, but there does exist a relation to the higher-order vertex. The order relation will then also apply to all of the vertices (in this vertex's content graph. This situation is depicted in FIG. 8, where $v$ is the vertex that represents the learning unit and $v_1, v_2$, are the vertices under consideration.

The function $\text{sortNav}(V)$ is the sort of the set $V$ in accordance with the order relation $<$. The following process is one method of implementing the function $\text{sortNav}(V)$:

1. $V_{\text{preTest}} = \{v \in V: \text{v.contentType} = \text{ist} \land \text{v.testType} = \text{pre}\}$; the set of all pretests.
2. $V = V - V_{\text{preTest}}$; remove all pretests from $V$.
3. $V_{\text{postTest}} = \{v \in V: \text{v.contentType} = \text{ist} \land \text{v.testType} = \text{post}\}$; the set of all posttests.
4. $V = V - V_{\text{postTest}}$; remove all posttests from $V$.
5. $V_{\text{preTest}} = \{v \in V: \text{v.contentType} = \text{ist} \land \text{v.testType} = \text{post}\}$; the set of all vertices that have a prerequisite relation directed toward them.
6. $V = V - V_{\text{preTest}}$; remove all vertices in $V_{\text{preTest}}$ from $V$.
7. $L = V_{\text{preTest}}$; add all pretests into the sorted list.
8. $L = L \cup \{v \in V: \text{v.contentType} = \text{isc}\}$; $V = V - L$; enlarge the sorted list to include all vertices that have a learning unit and then remove these vertices from $V$.
9. $L = L \cup \{v \in V: \text{v.contentType} = \text{isc}\}$; $V = V - L$; enlarge the sorted list to include all vertices that contain a learning unit and then remove these vertices from $V$.

All vertices that are connected to $v$ by an externally directed relation.

If the vertex contains a learning unit and one of the hierarchically subordinate vertices has not yet been visited,
enlarge the set to include the learning unit’s starting vertex using the micro-strategy “orientation only.” Otherwise, enlarge the set to include all vertices that are starting vertices of the content graph of v.

The operations and sorting function for the bottom-up strategy are the similar to the macro-strategy top-down and therefore are not repeated.

Linear macro-strategies represent a special case of the macro-strategies that have already been described. In linear macro-strategies, the elements of the sorted sets of vertices are offered for navigation sequentially, rather than simultaneously. This linearization may be applied to any combination of macro and micro-strategies.

The following description includes examples of how a micro-strategy may be realized. In this example, an orientation only micro-strategy is described.

The predicates for the micro-strategies may be defined as follows:

- **Visited(v)**: v.visited
- **Suggested(v)**: ∃(g,v,tr) ∈ E such that tr=prerequisite
- **CanNavigate(v)**: Suggested(v)
- **Done(v)**: v.visited=true

The vertex’s “visited” attribute is set.

All of the vertex’s prerequisites are already satisfied.

This may be used like Suggested.

\[
\text{Done}(v) = \begin{cases} \text{true} & : \text{LCOMP} = \{v,\text{graph},\text{comp},v,\text{graph},v,v,\text{visited}=\text{true} \\
\text{false} & : \text{LCOMP} = \{v,\text{graph},\text{comp},v,\text{graph},v,v,\text{visited}=\text{false} \end{cases}
\]

The maximum test score and the test score actually attained for the vertex are both set.

If the test is passed, the learner competences will be enlarged to include the competences of the graph, and all of the graph’s vertices will be set to “visited.”

If the test is not passed, all of the graph’s vertices are reset to “not visited.”

The micro-strategy orientation only may use a sorting function that is similar to sorting function for the macro-strategy top-down and, therefore, is not repeated.

The following is an example of the implementation of an example oriented micro-strategy. The predicates for this strategy are identical to those for the micro-strategy orientation only and are not repeated.

The functions may be defined as follows:

\[
\text{StartNodes}(g) = \{v \in \text{V} : \text{v.knowType=Orientation} \} \cup \{v \in \text{V} : \text{v.knowType=Orientation} \}
\]

The set of all vertices with knowledge type orientation, plus all vertices that have a prerequisite relation to a vertex with knowledge type orientation.

\[
\text{NextNodes}(v) = \emptyset
\]

For this micro-strategy, this is always the empty set. In other words, no successor vertices exist because all relevant vertices are contained in the set of starting vertices.

The operations may be defined as follows:

\[
\text{navigate}(v) : v,\text{visited} = \text{true}
\]

The vertex’s “visited” attribute is set to true.

\[
\text{testDone}(v, \text{MaxScore}, \text{ActScore}) : v,\text{mscore} = \text{MaxScore}, v,\text{ascore} = \text{ActScore}
\]

\[
\text{Done}(v) = \begin{cases} \text{true} & : \text{LCOMP} = \{v,\text{graph},\text{comp},v,\text{graph},v,v,\text{visited}=\text{true} \\
\text{false} & : \text{LCOMP} = \{v,\text{graph},\text{comp},v,\text{graph},v,v,\text{visited}=\text{false} \end{cases}
\]

The maximum test score and the test score actually attained for the vertex are both set.

If the test is passed, the learner competences will be enlarged to include the competences of the graph, and all of the graph’s vertices will be set to “visited.”

If the test is not passed, all of the graph’s vertices are reset to “not visited.”

The micro-strategy orientation only may use a sorting function that is similar to sorting function for the macro-strategy top-down and, therefore, is not repeated.

The following is an example of the implementation of an example oriented micro-strategy. The predicates for this strategy are identical to those for the micro-strategy orientation only and are not repeated.

The functions may be defined as follows:

\[
\text{StartNodes}(g) = \{v \in \text{V} : \text{v.knowType=Orientation} \} \cup \{v \in \text{V} : \text{v.knowType=Orientation} \}
\]

The set of all vertices with knowledge type orientation, plus all vertices that have a prerequisite relation to a vertex with knowledge type orientation.

\[
\text{NextNodes}(v) = \emptyset
\]

For this micro-strategy, this is always the empty set. In other words, no successor vertices exist because all relevant vertices are contained in the set of starting vertices.

The operations for the example-oriented micro-strategy are identical to those for the micro-strategy “orientation only,” and, therefore, are not repeated.
The sorting function for example-oriented is defined as follows:

\[ v_1 < v_2 \Leftrightarrow \begin{cases} v_1 <_{rem} v_2 & \text{if } v_1 \text{ is not an example} \\ v_1 <_{rem} v_2 & \text{if } v_1 \text{ is an example} \\ v_1 \text{ or } v_2 \in E \text{ is prereq} & \text{if } v_1 \text{ or } v_2 \text{ is an example} \\ v_1 \text{ or } v_2 \in E \text{ is prereq} & \text{if } v_1 \text{ or } v_2 \text{ is an example} \\ v_1 \text{ or } v_2 \in E \text{ is prereq} & \text{if } v_1 \text{ or } v_2 \text{ is an example} \\ \end{cases} \]

Steps for executing `sortNav(V)`:
1. \( V_{rem} = \{v \in V : \text{knowType} = \text{Example}\} \cup \{v \in V : v \text{ is not an example}\} \) the set of all vertices that contain examples, plus the prerequisites of these vertices.
2. \( V_{rem} = V - V_{rem} \) the remaining vertices from \( V \).
3. \( L_{rem} = \text{TopDown} (\text{sortNav}(V_{rem})) \) sort the set of examples using the sorting algorithm from the top-down strategy.
4. \( L_{rem} = \text{TopDown} (\text{sortNav}(V_{rem})) \) sort the set of remaining vertices using the sorting algorithm from the top-down strategy.
5. \( L = \text{Example} \cup L_{rem} \) form the union of the two sorted lists.
6. Return the sorted list \( L \) as the result.

The predicates, functions, and operations for the microstrategy explanation-oriented are identical to those for the microstrategy example-oriented, and, therefore, are not repeated. The sorting function for the explanation-oriented microstrategy is similar to the sorting function of the microstrategy example-oriented (the only difference being that explanations, rather than examples, are used to form the two sets).

The predicates, functions, and operations for the microstrategy action-oriented are identical to those for the microstrategy example-oriented, and, therefore, are not repeated. The sorting function for the action-oriented microstrategy is similar to the sorting function of the microstrategy example-oriented (the only difference being that actions, rather than examples, are used to form the two sets).

Anumber of implementations have been described. Nevertheless, it will be understood that various modifications may be made. For example, advantageous results may be achieved if the steps of the disclosed techniques are performed in a different order and/or if components in a disclosed system, architecture, device, or circuit are combined in a different manner and/or replaced or supplemented by other components. Accordingly, other implementations are within the scope of the following claims.

What is claimed is:
1. A method, performed via one or more processing devices, for use in an electronic learning (e-learning) system, the method comprising: dividing content associated with an e-learning course into two or more structural elements, the structural elements containing attributes, wherein at least one of the attributes relates to content of the structural elements; aggregating the structural elements into two or more levels, where a higher level structural element refers to a lower level structural element; assembling the structural elements into the e-learning course for use in the e-learning system; and obtaining a navigation strategy for the the e-learning course, the navigation strategy comprising a microstrategy that selectively presents content of the structural elements based on the attributes and a macrostrategy comprised of one or more microstrategies, wherein at least one of the attributes relates to the navigation strategy, and wherein the navigation strategy alters an attribute relating to the navigation strategy when presenting content of the structural elements.

2. The method of claim 1, wherein the structural elements comprise a knowledge item.

3. The method of claim 2, wherein the knowledge item comprises content to illustrate an aspect of a topic.

4. The method of claim 2, wherein the knowledge item comprises content to test an aspect of a topic.

5. The method of claim 2, wherein the knowledge item comprises one or more text, a table, an illustration, a graphic, an animation, an audio clip, and/or video clip.

6. The method of claim 1, wherein the structural elements comprise a learning unit which refers to one or more knowledge items to represent a thematically-coherent unit of information.

7. The method of claim 1, wherein the structural elements comprise a sub-course which refers to one or more of a knowledge item, a learning unit, and another sub-course.

8. The method of claim 1, wherein the structural elements comprise a course which refers to one or more of a knowledge item, a learning unit, and a sub-course.

9. The method of claim 1, wherein the structural elements are usable in more than one e-learning course.

10. The method of claim 1, wherein the structural elements comprise extensible markup language files.

11. The method of claim 1, further comprising: tagging the structural elements with metadata that is used to assemble the structural elements, the metadata defining the attributes.

12. The method of claim 11, wherein the metadata corresponds to knowledge of orientation.

13. The method of claim 12, wherein the metadata corresponds to knowledge of explanation.

14. The method of claim 12, wherein the metadata corresponds to knowledge of reference.

15. The method of claim 12, wherein the metadata corresponds to knowledge of action.

16. The method of claim 12, wherein the metadata corresponds to a competency indicative of performance of a learner who traverses the e-learning course.

17. The method of claim 1, further comprising: providing one or more relations to indicate dependencies between structural elements.

18. The method of claim 17, wherein the one or more relations comprise a directional relation that is true in one direction only.

19. The method of claim 17, wherein the one or more relations comprise a non-directional relation that is true in either of two directions.

20. The method of claim 17, wherein the one or more relations comprise a subject taxonomic relation.

21. The method of claim 20, wherein the one or more relations comprise a hierarchical relation.

22. The method of claim 21, wherein the hierarchical relation comprises a part/whole relation or an abstraction relation.

23. The method of claim 20, wherein the subject taxonomic relation comprises an associative relation.

24. The method of claim 23, wherein the associative relation comprises a relation that is one of determines,
The system of claim 28, wherein the metadata comprises knowledge of action.

The system of claim 28, wherein the metadata comprises a competency to indicate performance of a learner who traverses the e-learning course.

The system of claim 28, wherein a relation is used to indicate dependencies between structural elements.

The system of claim 24, wherein the relation is directional and true in one direction only.

The system of claim 24, wherein the relation is non-directional and true in one of two directions.

The system of claim 24, wherein the relation comprises a subject taxonomic relation.

The system of claim 24, wherein the subject taxonomic relation comprises a hierarchical relation.

The system of claim 24, wherein the hierarchical relation is one of a part/whole relation and an abstraction relation.

The system of claim 24, wherein the subject taxonomic relation comprises an associative relation.

The system of claim 24, wherein the associative relation comprises one of determines, side-by-side, alternative to, opposite to, precedes, context of, process of, values, means of, and affinity.

The system of claim 24, wherein the relation comprises a non-subject taxonomic relation.

The system of claim 24, wherein the non-subject taxonomic relation comprises a relation that indicates that a structural element belongs to another structural element.

The system of claim 24, wherein a relation comprises one of determines, side-by-side, alternation, or is directional and true in one direction only.

The system of claim 24, wherein the relation comprises a relation that indicates a taxonomic relation and an abstraction relation.

The system of claim 24, wherein the non-subject taxonomic relation comprises a relation that indicates a taxonomic relation.

An electronic learning (e-learning) system comprising:

- a content repository for storing a plurality of structural elements associated with an e-learning course, the structural elements being aggregated into two or more levels, where a higher level structural element refers to a lower level structural element, the structural elements containing attributes, wherein at least one of the attributes relates to content of the structural elements; and
- a content player for assembling the structural elements into the e-learning course for presentation to a learner, the content player presenting the e-learning course using a navigation strategy, the navigation strategy comprising a microstrategy that selectively presents content of the structural elements based on the attributes and a macrostrategy comprised of one or more microstrategies, wherein at least one of the attributes relates to the navigation strategy, and wherein the navigation strategy alters an attribute relating to the navigation strategy when presenting content of the structural elements.

The system of claim 28, wherein a lowest level structural element comprises a knowledge item.

The system of claim 29, wherein the knowledge item illustrates an aspect of a topic.

The system of claim 29, wherein the knowledge item tests an aspect of a topic.

The system of claim 29, wherein the knowledge item includes one or more of text, a table, an illustration, a graphic, an animation, an audio clip, and a video clip.

The system of claim 28, wherein the structural elements comprise a learning unit which refers to one or more knowledge items to represent a thematically coherent unit of information.

The system of claim 28, wherein the structural elements comprise a sub-course which refers to one or more of a knowledge item, a learning unit, and another sub-course.

The system of claim 28, wherein the structural elements comprise a course which refers to one or more of a knowledge item, a learning unit, and a sub-course.

The system of claim 28, wherein the structural elements are usable in more than one course.

The system of claim 28, wherein the structural elements comprise extensible markup language files.

The system of claim 28, wherein the structural elements are tagged with metadata to assemble the structural elements, the metadata defining the attributes.

The system of claim 38, wherein the metadata comprises knowledge of orientation.

The system of claim 39, wherein the metadata comprises knowledge of explanation.

The system of claim 38, wherein the metadata comprises knowledge of reference.

The system of claim 38, wherein the metadata comprises knowledge of action.

The system of claim 38, wherein the metadata comprises a competency to indicate performance of a learner who traverses the e-learning course.

The system of claim 28, wherein a relation is used to indicate dependencies between structural elements.

The system of claim 24, wherein the relation is directional and true in one direction only.

The system of claim 24, wherein the relation is non-directional and true in one of two directions.

The system of claim 24, wherein the relation comprises a subject taxonomic relation.

The system of claim 24, wherein the subject taxonomic relation comprises a hierarchical relation.

The system of claim 24, wherein the subject taxonomic relation comprises an associative relation.

The system of claim 24, wherein the associative relation comprises one of determines, side-by-side, alternative to, opposite to, precedes, context of, process of, values, means of, and affinity.

The system of claim 24, wherein the relation comprises a non-subject taxonomic relation.

The system of claim 24, wherein the non-subject taxonomic relation comprises a relation that indicates that a structural element belongs to another structural element.

One or more machine-readable media for storing course data for access by an application program that is executable by a content player of an electronic learning (e-learning) system, the course data comprising:

- a plurality of structural elements aggregated into two or more levels, where a higher level structural element refers to a lower level structural element, the structural elements comprising content for presentation to a learner via the e-learning system;
- metadata associated with the structural elements, the metadata defining attributes, wherein at least one of the attributes relates to content of the structural elements; and
- a plurality of relations to indicate dependencies between two or more of the structural elements; and
- a navigation strategy comprised of a microstrategy that selectively presents content of the structural elements based on the attributes and a macrostrategy comprised of one or more microstrategies, wherein at least one of the attributes relates to the navigation strategy, and wherein the navigation strategy is configured to alter an attribute relating to the navigation strategy when presenting content of the structural elements.

The machine-readable media of claim 55, wherein a lowest level structural element comprises a knowledge item.

The machine-readable media of claim 56, wherein the knowledge item illustrates an aspect of a topic.

The machine-readable media of claim 56, wherein the knowledge item tests an aspect of a topic.

The machine-readable media of claim 56, wherein the knowledge item comprises one or more of text, a table, an illustration, a graphic, an animation, an audio clip, and a video clip.
60. The machine-readable media of claim 55, wherein the structural elements comprise a learning unit which refers to one or more knowledge items to represent a thematically-coherent unit of information.

61. The machine-readable media of claim 55, wherein the structural elements comprise a sub-course which refers to one or more of a knowledge item, a learning unit, and another sub-course.

62. The machine-readable media of claim 55, wherein the structural elements comprise a course which refers to one or more of a knowledge item, a learning unit, and a sub-course.

63. The machine-readable media of claim 55, wherein the structural elements are usable in more than one course.

64. The machine-readable media of claim 55, wherein the structural elements comprise extensible markup language files.

65. The machine-readable media of claim 55, wherein the structural elements are tagged with the metadata to assemble the structural elements.

66. The machine-readable media of claim 65, wherein the metadata comprises knowledge of orientation.

67. The machine-readable media of claim 66, wherein the metadata comprises knowledge of explanation.

68. The machine-readable media of claim 66, wherein the metadata comprises knowledge of action.

69. The machine-readable media of claim 66, wherein the metadata comprises knowledge of reference.

70. The machine-readable media of claim 66, wherein the metadata comprises knowledge of action.

71. The machine-readable media of claim 55, wherein at least one of the relations is directional and true in one direction only.

72. The machine-readable media of claim 55, wherein at least one of the relations is non-directional and true in one of two directions.

73. The machine-readable media of claim 55, wherein at least one of the relations comprises a subject taxonomic relation.

74. The machine-readable media of claim 73, wherein the subject taxonomic relation comprises a hierarchical relation.

75. The machine-readable media of claim 74, wherein the hierarchical relation comprises a part/whole relation or an abstraction relation.

76. The machine-readable media of claim 73, wherein the subject taxonomic relation comprises an associative relation.

77. The machine-readable media of claim 76, wherein the associative relation comprises one of determines, side-by-side, alternative to, opposite to, precedes, context of, process of, values, means of, and affinity.

78. The machine-readable media of claim 55, wherein at least one of the relations comprises a non-subject taxonomic relation.

79. The machine-readable media of claim 78, wherein the non-subject taxonomic relation comprises a relation that indicates a structural element should be completed before proceeding to a related structural element.

80. The machine-readable media of claim 78, wherein the non-subject taxonomic relation comprises a relation that indicates that a structural element belongs to another structural element.
